8. Summary

Introduction

A large community.

- Self-driving cars accelerate development and extend needs and scope for automotive modeling.
- Large user groups for Modelica.
- Vehicular systems lend themselves well to component-based DAE modeling.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- This lecture aims to provide an overview of some model components common for automotive modeling.
- Many opportunities for course projects in this area.

Model Components for a Vehicle

A vehicle model typically consists of more or less complex models of the following components:

- Powertrain and braking systems,
- Wheels and tire dynamics,
- Steering and suspension dynamics,
- Chassis dynamics.

In addition: Driver and environment modeling important for automotive simulations.

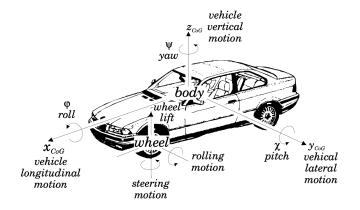

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Models for Different Purposes

- What is the purpose of the vehicle model?
- Wide range of applications for vehicle models, e.g.,
 - simulation (vehicle design, validation, control design),
 - dynamic optimization,
 - code generation for embedded real-time execution.
- What level of fidelity is required to capture essential dynamics?
- Models for dynamic optimization imply certain considerations (e.g., differentiation).

Vehicle Coordinate Frames

An illustration of involved vehicle coordinate frames and variables from [Kiencke & Nielsen, 2005]:

Automotive Modeling—An Overview of Model Components

- 7. Experiments and model calibration

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

8. Summary

Propulsion System for a Vehicle

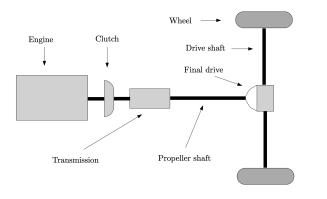

- Drivetrain includes all components required to deliver power to the driving wheels of the vehicle from the engine/motor.
- Powertrain includes drivetrain and engine/motor.
 - Internal combustion engines (diesel, gasoline, ethanol, etc.).

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- Battery-electric vehicles with electric motor.
- Hybrid vehicles (internal combustion engine and electric motor).
- Fuel-cell electric vehicles.
- Dedicated drive cycles (driving missions) for system and control design.

Vehicle Powertrain Model

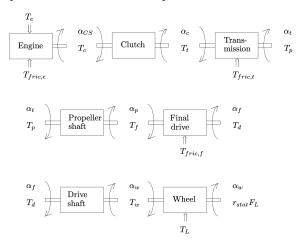

- Engine/motor, clutch, transmission (gear box), shafts, and wheels.
- Often non-linear flexibilities in clutch and shafts.
- Illustration of a powertrain model from [Kiencke & Nielsen, 2005] for a rear-wheel driven vehicle:

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Powertrain Model

 Rotational angles and torques involved in a powertrain model from [Kiencke & Nielsen, 2005]:

► F_L is the resulting traction force on the wheel moving the vehicle forward.

Aerodynamic and Rolling Resistance

 A low-complexity model for aerodynamic resistance, or air drag (v speed, ρ_{air} air density) [Kiencke & Nielsen, 2005]:

$$F_{\rm wind} = \frac{1}{2} c_{\rm air} A_L \rho_{\rm air} v^2$$

with c_{air} drag coefficient and A_L vehicle cross-section area.

- Relation based on fluid dynamics (Lord Rayleigh).
- Tabulated values for different vehicles. Average values of drag area c_{air}A_L for a passenger car are 0.5–2.5 m².
- Complex models for aerodynamic resistance (cf. racing cars).
- ► A low-complexity model for rolling resistance (*m* mass):

$$F_{\rm R}=m(c_1+c_2v)$$

where coefficients c_1 and c_2 depend on, e.g., tire properties.

Propulsion Forces

- ► Gravity force contributes with -mg sin(\(\chi_r\) road\)) for a road with angle \(\chi_r\) road.
- Summing the forces involved in the vehicle propulsion in the longitudinal direction gives using Newton's second law of motion:

$$m\dot{v} = \underbrace{F_{L}}_{\text{Traction force}} \underbrace{-F_{wind} - F_{R} - mg \sin(\chi_{road})}_{\text{Opposing forces}}$$

8. Summary

Braking Systems for a Vehicle

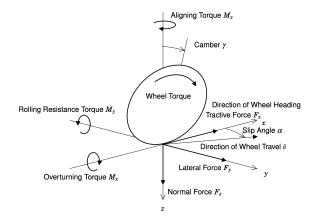

Brakes for reducing speed of the vehicle, often friction-based with mechanical device.

- Disc brake or drum brake.
- Regenerative braking by electric motors (energy recovery by converting the kinetic energy).
- Many control systems related to braking:
 - Anti-lock braking system (ABS), maintain traction by avoiding wheel lock during braking.

- Yaw control and Electronic Stability Control (ESC), individual-wheel braking.
- Autonomous emergency braking systems.

Wheel Dynamics

 Forces and torques involved on a wheel, illustration from Ph.D. Thesis [Svendenius, 2007] based on SAE convention.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Wheel Slips

- Longitudinal slip ratio κ and lateral slip angle α for the wheel.
- Let R_w be the wheel radius, ω_i the angular velocity, and v_{x,i}, v_{y,i} the longitudinal and lateral velocities for wheel i.
- Longitudinal slip ratio [Pacejka, 2006]:

$$\kappa_i = \frac{R_w \omega_i - v_{x,i}}{v_{x,i}}, \ i \in \{f, r\} \text{ or } \{1, 2, 3, 4\}$$

Lateral slip angle with relaxation length [Pacejka, 2006]:

$$\dot{\alpha}_i \frac{\sigma}{v_{\mathsf{x},i}} + \alpha_i = -\arctan\left(\frac{v_{\mathsf{y},i}}{v_{\mathsf{x},i}}\right), \ i \in \{f, r\} \text{ or } \{1, 2, 3, 4\}$$

where σ is the relaxation length.

• Body slip $\beta = \arctan\left(\frac{v_y}{v_x}\right)$, where v_x , v_y are longitudinal and lateral velocities at vehicle center of mass.

8. Summary

Tire-Road Interaction Models

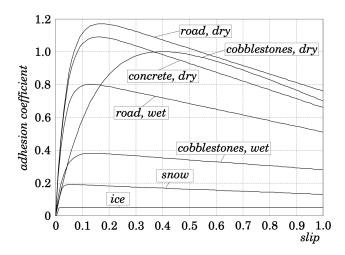

- Tire important part of the wheel.
- Friction between tire and road surface allows acceleration and deceleration of the vehicle as well as cornering (longitudinal F_x and lateral forces F_y).
- A vast plethora of models exist for modeling such dynamics.
- Dynamics depends on tire, road surface, temperature, normal load, etc. Thus, *tire-road interaction models*.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Longitudinal Tire Forces

Longitudinal tire forces as function of slip for different road surfaces, from [Kiencke & Nielsen, 2005].

▲□▶ ▲□▶ ▲臣▶ ★臣▶ = 臣 = のへで

A first, linear model of the longitudinal F_x and lateral F_y tire forces:

$$F_x = C_\kappa \kappa$$
$$F_y = C_\alpha \alpha$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

• C_{κ} and C_{α} are the tire longitudinal and cornering stiffness, respectively.

Tire–Road Interaction Models

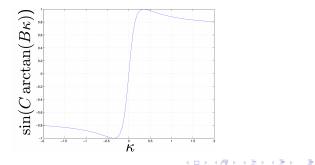

Pacejka's Magic Formula [Pacejka, 2006] slip-based model:

$$F_{x0} = \mu_x F_z \sin(C_x \arctan(B_x \kappa - E_x (B_x \kappa - \arctan(B_x \kappa))))$$

 $F_{y0} = \mu_y F_z \sin(C_y \arctan(B_y \alpha - E_y (B_y \alpha - \arctan(B_y \alpha))))$

Empirical model, calibrated based on experimental data.

 Hans B. Pacejka (TU Delft), book "Tyre and Vehicle Dynamics", co-founder of journal Vehicle System Dynamics.

Tire-Road Interaction Models: Combined Slip

Friction ellipse for modeling of lateral forces (often with F_x as input):

$$F_{y} = F_{y0} \sqrt{1 - \left(\frac{F_{x}}{\mu_{x} F_{z}}\right)^{2}}$$

Weighting functions for combined longitudinal and lateral tire forces [Pacejka, 2006]:

$$B_{x\alpha} = B_{x1} \cos(\arctan(B_{x2}\kappa)), \ G_{x\alpha} = \cos(C_{x\alpha} \arctan(B_{x\alpha}\alpha)),$$

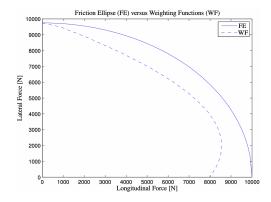

$$F_x = F_{x0}G_{x\alpha}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

 Corresponding weighting functions and parameters for the lateral force.

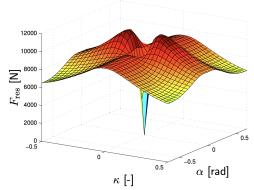

Friction Ellipse vs. Weighting Functions

- Comparison between Friction Ellipse and Weighting Functions from [Berntorp, 2013] for combined tire forces (α = 14 deg.).
- Differences most prominent for low lateral tire forces.

Empirical Pacejka Parameters and Weighting Functions

Resulting tire-force surface from [Berntorp, Olofsson et al., 2013], with empirical parameters from [Pacejka, 2006].

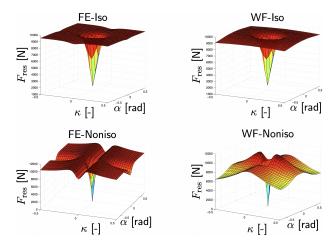

Resulting Tire Force

Tire-Road Interaction Model Calibration

 Tire-force surfaces from [Berntorp, Olofsson et al., 2013], with empirical parameters from [Pacejka, 2006] for friction ellipse (FE) and weighting functions (WF).

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○三 の々で

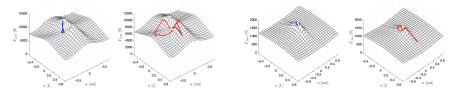

Force-Slip Diagrams

Force-slip diagrams [Berntorp, Olofsson, et al, 2014] illustrate the normalized resultant tire-force F_{res}, as function of κ and α, where

$$F_{\rm res} = \sqrt{F_x^2 + F_y^2}$$

The trace from a vehicle maneuver is drawn on this surface.

- Gives valuable information about utilization of the tire-road friction potential.
- Examples for dry asphalt (left) and smooth ice (right) for a specific vehicle maneuver [Olofsson, Berntorp et al., 2013]:

◆□ ▶ ◆□ ▶ ◆三 ▶ ◆三 ▶ ● 三 ● ● ●

Other Tire–Road Interaction Models

- The tire parameters can be scaled/modified to represent different road surfaces [Braghin et al., 2006].
- Models commonly used for simulation, not always sufficient for optimization.
- Friction is a complex phenomenon (recall previous lecture).
- Other common models are, e.g., Brush models, Dugoff / HSRI model, and Burckhardt model [Kiencke & Nielsen, 2005].
- Also transient friction models like LuGre and SWIFT have been proposed and adapted to tire modeling [Pacejka, 2006; Kiencke & Nielsen, 2005; Svendenius, 2007].

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

8. Summary

Steering Dynamics

The steering ratio: ratio between turning the steering wheel and the actual rotation of the wheels.

► Usually in the range of 10–20:1 for passenger cars.

- The camber angle: angle between vertical axis of wheel and vertical axis of vehicle, with perspective from the front.
 - Affects the handling dynamics of the car in interaction with the suspension system, often utilized in racing.

Steering Kinematics—Ackermann Turning

- Left and right wheels on the axle moving with different curve radii.
- Steering mechanism known as Ackermann steering geometry (horse carriages, Georg Lankensperger, Rudolph Ackermann, 1817-1818).
- Quasi-static considerations for determining steering kinematics. Implications on vehicle dynamics.

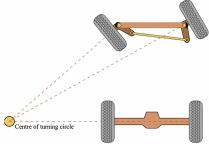

Figure source: Wikimedia Commons, CC BY-SA 3.0

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ ○ ○ ○

Suspension Dynamics

- Often used concepts:
 - Unsprung mass: Wheels and the suspension system.
 - Sprung mass: Carried by the suspension system (vehicle body).
- A first, linear model for a four-wheeled vehicle would be rotational inertia-spring-damper systems for roll and pitch directions.
- Moment τ_{ϕ} produced by the suspension system in the roll direction modeled by

$$\tau_{\phi} = (K_{\phi,f} + K_{\phi,r})\phi + (D_{\phi,f} + D_{\phi,r})\dot{\phi}$$

• Moment τ_{θ} in the pitch direction modeled according to

$$\tau_{\theta} = K_{\theta}\theta + D_{\theta}\dot{\theta}$$

- ロ ト - 4 回 ト - 4 □

where K and D are stiffness and damping parameters.

Dynamic Equations for Load Transfer

- A suspension system implies load transfer when accelerating/decelerating (i.e., time-varying normal forces).
- Dynamic equations for longitudinal load transfer:

$$(F_{z,1}+F_{z,2})I_f - (F_{z,3}+F_{z,4})I_r = K_{\theta}\theta + D_{\theta}\dot{\theta}, \quad \sum_{i=1}^4 F_{z,i} = mg$$

where $F_{z,i}$, $i \in \{1, 2, 3, 4\}$, are the normal forces on each wheel and I_f , I_r are front and rear distances from the wheel axle to center of mass.

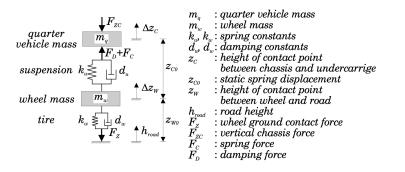

Lateral load transfer:

$$-w(F_{z,1} - F_{z,2}) = K_{\phi,f}\phi + D_{\phi,f}\dot{\phi},$$
$$-w(F_{z,3} - F_{z,4}) = K_{\phi,r}\phi + D_{\phi,r}\dot{\phi}$$

where w is half of the vehicle track width.

Quarter Model for Suspension Dynamics

- The quarter model is common for modeling and designing suspension systems (including control for active damping).
- One version from [Kiencke & Nielsen, 2005] illustrated in the figure.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

8. Summary

Characteristics of Chassis Dynamics

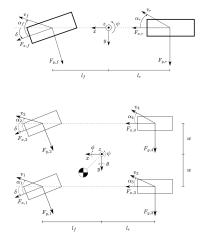

- Model equations for the chassis dynamics derived from analytical mechanics.
- Newton-Euler or Euler-Lagrange approach (recall previous lectures) to establish a differential-algebraic equation (DAE) system.
- Principles are straightforward, but often a time-consuming and slightly tedious process to derive the equations.

- ロ ト - 4 回 ト - 4 □

- Tools for symbolic manipulation of variables useful.
- Extensive libraries with models of varying fidelity exist.

Chassis Dynamic Models

- Varying complexity of chassis models possible.
- Examples for a four-wheel vehicle include the simplified single-track model (upper figure) and the double-track model (lower figure).
- Double-track model:
 - Roll and pitch dynamics and associated load transfer.
 - Control inputs: Steering angle δ and wheel torques T₁, T₂, T₃, and T₄.

(日)

Single-Track Vehicle Model

Single-track model equations [Berntorp, Olofsson et al., 2014]:

$$\begin{split} \dot{v}_x - v_y \dot{\psi} &= \frac{1}{m} (F_{x,f} \cos(\delta) + F_{x,r} - F_{y,f} \sin(\delta)) = \frac{F_X}{m}, \\ \dot{v}_y + v_x \dot{\psi} &= \frac{1}{m} (F_{y,f} \cos(\delta) + F_{y,r} + F_{x,f} \sin(\delta)) = \frac{F_Y}{m}, \\ I_{zz} \ddot{\psi} &= I_f F_{y,f} \cos(\delta) - I_r F_{y,r} + I_f F_{x,f} \sin(\delta) = M_Z, \end{split}$$

 F_X, F_Y, and M_Z are the global forces, δ is the steering angle, and I_{zz} is the inertia about the z-axis.

Longitudinal tire forces F_x (or wheel torques) and steering angle δ as inputs.

Double-Track Model—Translational Motion

- Equations for a double-track vehicle model more extensive, see [Berntorp, 2013] for a full derivation.
- The model equations for translation motion along x and y are:

$$\begin{split} \dot{v}_x - v_y \dot{\psi} &= h \Big(\sin\left(\theta\right) \cos\left(\phi\right) (\dot{\psi}^2 + \dot{\phi}^2 + \dot{\theta}^2) - \sin\left(\phi\right) \ddot{\psi} - 2\cos\left(\phi\right) \dot{\phi} \dot{\psi} \\ &- \cos\left(\theta\right) \cos\left(\phi\right) \ddot{\theta} + 2\cos\left(\theta\right) \sin\left(\phi\right) \dot{\theta} \dot{\phi} \\ &+ \sin\left(\theta\right) \sin\left(\phi\right) \ddot{\phi} \Big) + \frac{F_X}{m} \\ \dot{v}_y + v_x \dot{\psi} &= h \Big(-\sin\left(\theta\right) \cos\left(\phi\right) \ddot{\psi} - \sin\left(\phi\right) \dot{\psi}^2 - 2\cos\left(\theta\right) \cos\left(\phi\right) \dot{\theta} \dot{\psi} \\ &+ \sin\left(\theta\right) \sin\left(\phi\right) \dot{\phi} \dot{\psi} - \sin\left(\phi\right) \dot{\phi}^2 + \cos\left(\phi\right) \ddot{\phi} \Big) + \frac{F_Y}{m}, \end{split}$$

Double-Track Model—Global Forces

The global forces for the translational motion are:

$$F_{X} = F_{x,1} \cos(\delta) - F_{y,1} \sin(\delta) + F_{x,2} \cos(\delta) - F_{y,2} \sin(\delta) + F_{x,3} + F_{x,4},$$

$$F_{Y} = F_{x,1} \sin(\delta) + F_{y,1} \cos(\delta) + F_{x,2} \sin(\delta) + F_{y,2} \cos(\delta) + F_{y,3} + F_{y,4}$$

◆□▶ ◆□▶ ◆ 臣▶ ◆ 臣▶ ○ 臣 ○ の Q @

Double-Track Model—Yaw Dynamics

Let *I_{xx}*, *I_{yy}*, and *I_{zz}* be the inertia for the respective direction.
 The dynamic equation for ψ (yaw motion) is given by:

$$\ddot{\psi}(I_{xx}\sin(\theta)^2 + \cos(\theta)^2(I_{yy}\sin(\phi)^2 + I_{zz}\cos(\phi)^2)) = M_Z - h\Big(F_X\sin(\phi) + F_Y\sin(\theta)\cos(\phi)\Big),$$

where the global moment is:

$$M_{Z} = I_{f} \left(F_{x,1} \sin(\delta) + F_{x,2} \sin(\delta) + F_{y,1} \cos(\delta) + F_{y,2} \cos(\delta) \right) + w_{f} \left(-F_{x,1} \cos(\delta) + F_{x,2} \cos(\delta) + F_{y,1} \sin(\delta) - F_{y,2} \sin(\delta) \right) - I_{r} (F_{y,3} + F_{y,4}) - w_{r} (F_{x,3} + F_{x,4}).$$

Double-Track Model—Pitch Dynamics

• The dynamic equation for θ (pitch motion) is given by:

$$\begin{aligned} \ddot{\theta}(I_{yy}\cos(\phi)^2 + I_{zz}\sin(\phi)^2) &= -K_{\theta}\theta - D_{\theta}\dot{\theta} \\ &+ h\Big(mg\sin(\theta)\cos(\phi) - F_X\cos(\theta)\cos(\phi)\Big) \\ &+ \dot{\psi}\Big(\dot{\psi}\sin(\theta)\cos(\theta)\big(\Delta I_{xy} \\ &+ \cos(\phi)^2\Delta I_{yz}\big) - \dot{\phi}(\cos(\theta)^2 I_{xx} + \sin(\phi)^2\sin(\theta)^2 I_{yy} \\ &+ \sin(\theta)^2\cos(\phi)^2 I_{zz}\big) - \dot{\theta}\Big(\sin(\theta)\sin(\phi)\cos(\phi)\Delta I_{yz}\Big)\Big) \end{aligned}$$

where $\Delta I_{xy} = I_{xx} - I_{yy}$ and $\Delta I_{yz} = I_{yy} - I_{zz}$.

Double-Track Model—Roll Dynamics

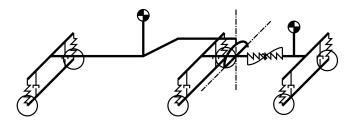

• The dynamic equation for ϕ (roll motion) is given by:

$$\begin{split} \ddot{\phi}(I_{xx}\cos{(\theta)^2} + I_{yy}\sin{(\theta)^2}\sin{(\phi)^2} + I_{zz}\sin{(\theta)^2}\cos{(\phi)^2}) \\ &= -K_{\phi}\phi - D_{\phi}\dot{\phi} + h(F_Y\cos{(\phi)}\cos{(\theta)} + mg\sin{(\phi)}) \\ &+ \dot{\psi}\Delta I_{yz}\Big(\dot{\psi}\sin{(\phi)}\cos{(\phi)}\cos{(\theta)} + \dot{\phi}\sin{(\theta)}\sin{(\phi)}\cos{(\phi)}\Big) \\ &+ \dot{\psi}\dot{\theta}(\cos{(\phi)^2}I_{yy} + \sin{(\phi)^2}I_{zz}). \end{split}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Tractor-Semitrailer Combinations (1/2)

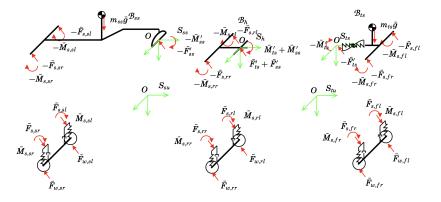

- Corresponding models can also be derived for vehicles with additional degrees-of-freedom.
- Example in the figure: 9-DoF model from [Gäfvert & Lindgärde, 2001] for a tractor-semitrailer truck.
- Extensive model equations, beneficial with computer manipulation.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Tractor-Semitrailer Combinations (2/2)

- Principles for modeling are the same, though with additional involved coordinate frames.
- Illustration of tractor-semitrailer model with free-body diagram from [Gäfvert & Lindgärde, 2001]:

8. Summary

Summary

- Automotive modeling covers many different model areas.
- Differential-algebraic equation systems natural for description of the model dynamics.
- Modelica offers a language for such model descriptions.
- Associated tools enable model simulations and dynamic optimization of DAEs.
- Mathias Strandberg from Modelon will describe how automotive modeling and simulation can be done using Modelica in the tool *Modelon Impact* during the lecture on May 5.
